

RESEARCH AND DATASET

It focuses on analyzing Amazon customer reviews to understand how customers feel about different products. Sentiment Analysis is used to classify reviews as Positive, Negative, or Neutral, helping businesses understand customer satisfaction and identify areas for improvement.

To analyze the review text, the project uses Natural Language Processing (NLP), which cleans, processes, and interprets human language before determining the sentiment. NLP is widely used in applications such as chatbots, Google Translate, voice assistants, spam detection, and recommendation systems.

The dataset contains 34,624 customer reviews with 10 columns, including product name, brand, review date, rating, review title, review text, recommendation status, helpful votes, cleaned review text, and sentiment labels. The dataset is well-organized, with only 6 missing values in the review title column, making it reliable for analysis.

The project also explains the Buyer Journey, which includes Awareness, Consideration, Purchase, and Post-Purchase stages. Customer reviews influence buyers during every stage by helping them compare products and make informed decisions.

By analyzing review sentiments, creating visualizations, and identifying common trends, the project provides valuable insights that help businesses improve their products, enhance customer satisfaction, and support future buyers in choosing the right products.
